# What is in Common?

- **Large-scale:**
  - #nodes ranges from 10M to 10B.
  - #edges ranges from 100M to 100B.
- **Tasks**
  - **Node-level:** User/item/paper classification.
  - **Link-level:** Recommendation, completion.
- **Todays' lecture**
  - **Scale up GNNs to large graphs!**

# Why is it Hard?

- **Recall:** How we usually train an ML model on large data ( $N=\#\text{data}$  is large)
- **Objective:** Minimize the averaged loss

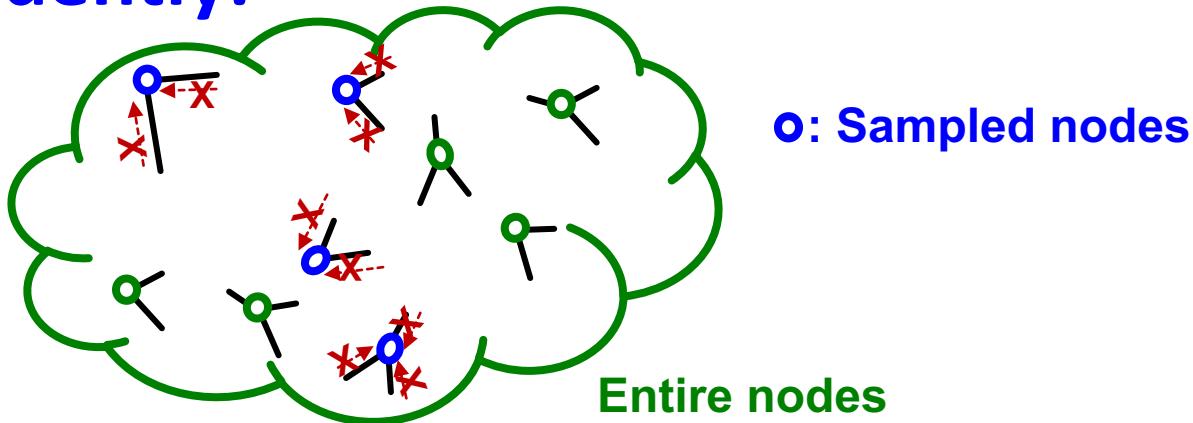

$$\ell(\boldsymbol{\theta}) = \frac{1}{N} \sum_{i=0}^{N-1} \ell_i(\boldsymbol{\theta})$$

- $\boldsymbol{\theta}$ : model parameters,  $\ell_i(\boldsymbol{\theta})$ : loss for  $i$ -th data point.
- We perform **Stochastic Gradient Descent (SGD)**.
  - Randomly sample  $M$  ( $<< N$ ) data (**mini-batches**).
  - Compute the  $\ell_{sub}(\boldsymbol{\theta})$  over the  $M$  data points.
  - Perform SGD:  $\boldsymbol{\theta} \leftarrow \boldsymbol{\theta} - \nabla \ell_{sub}(\boldsymbol{\theta})$

# Why is it Hard?

What if we use the standard SGD for GNN?

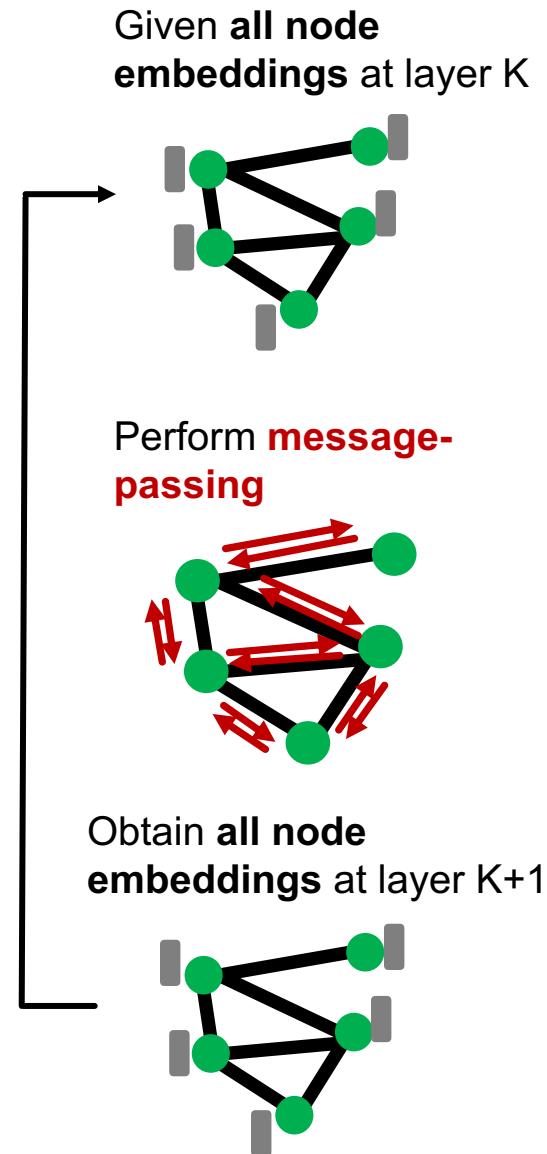

- In mini-batch, we sample  $M$  ( $<< N$ ) nodes independently:

- Sampled nodes tend to be isolated from each other.
- Recall:** GNN generate node embeddings by aggregating neighboring node features.
  - GNN does not access to neighboring nodes within the mini-batch!
- Standard SGD cannot effectively train GNNs.**

# Why is it Hard?

- **Naïve full-batch implementation:** Generate embeddings of all the nodes **at the same time.**
  - Load **the entire graph and features**
  - **At each GNN layer:**
    - Compute embeddings of all nodes using all the node embeddings from the previous layer.
  - Compute the loss
  - Perform gradient descent

# Why is it Hard?

- However, **Full-batch** implementation is **not feasible** for a large graphs. **Why?**
- Because we want to use GPU for fast training, but GPU memory is extremely limited (only 10GB--20GB).
  - **The entire graph and the features cannot be loaded on GPU.**

Slow computation,  
large memory

CPU  
1TB—10TB

Fast computation,  
limited memory

GPU  
10GB—20GB

# Today's Lecture

We introduce **three methods for scaling up GNNs**:

- Two methods perform message-passing over **small subgraphs in each mini-batch**; only the subgraphs need to be loaded on a GPU at a time.
  - **Neighbor Sampling** [Hamilton et al. NeurIPS 2017]
  - **Cluster-GCN** [Chiang et al. KDD 2019]
- One method **simplifies a GNN into feature-preprocessing operation** (can be efficiently performed even on a CPU)
  - **Simplified GCN** [Wu et al. ICML 2019]

# GraphSAGE Neighbor Sampling: Scaling up GNNs

CS224W: Machine Learning with Graphs

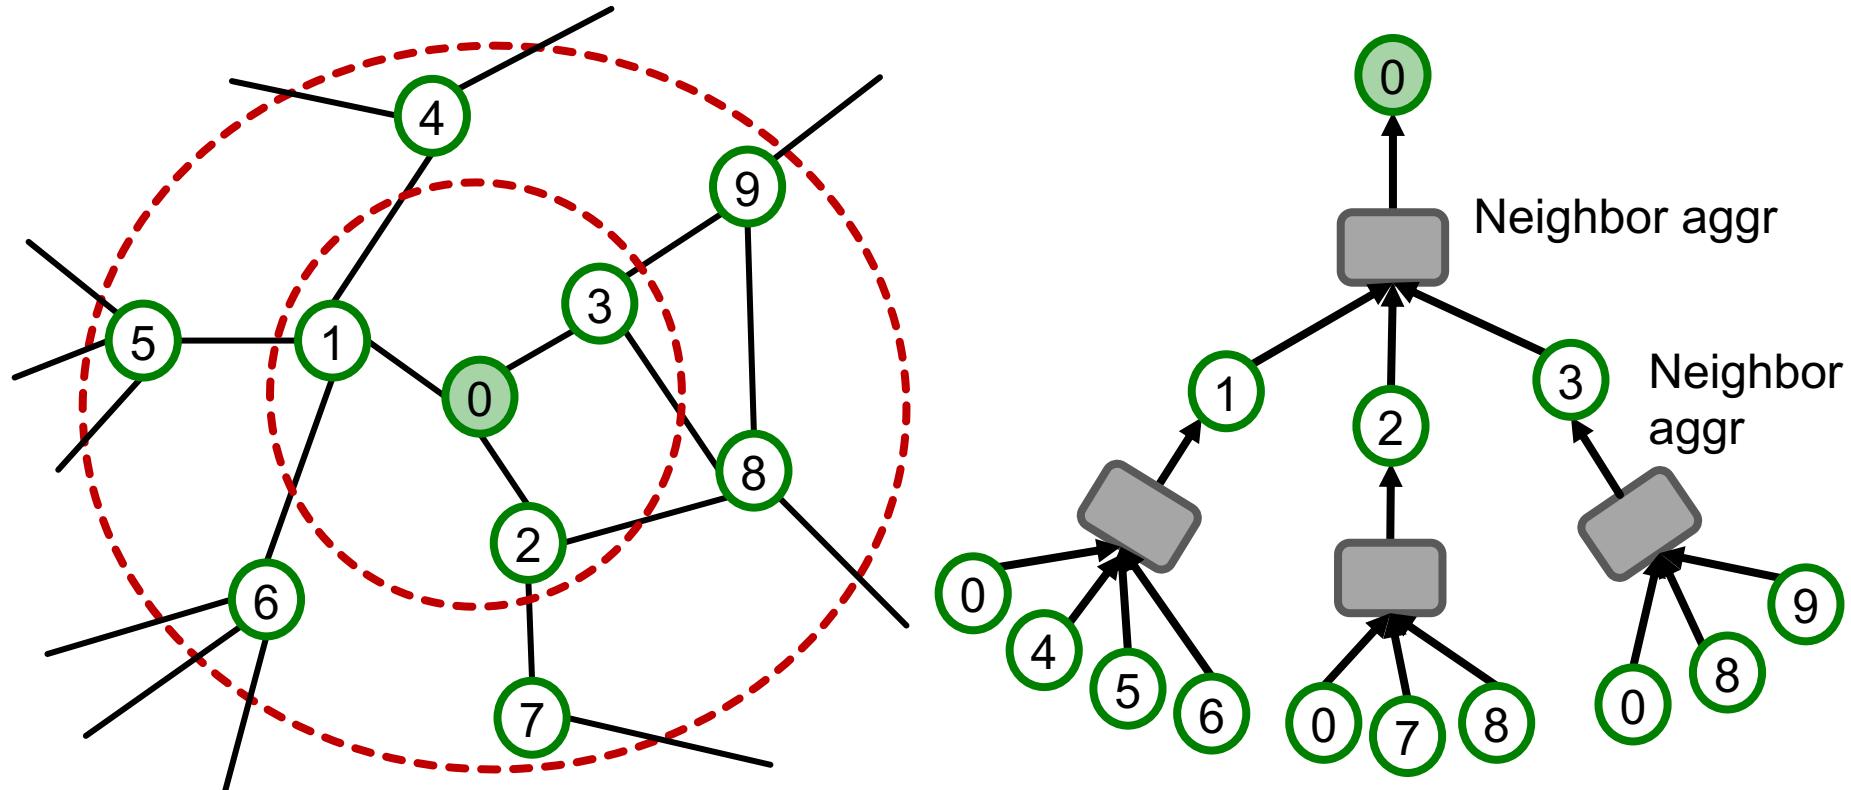

Jure Leskovec, Stanford University

<http://cs224w.stanford.edu>

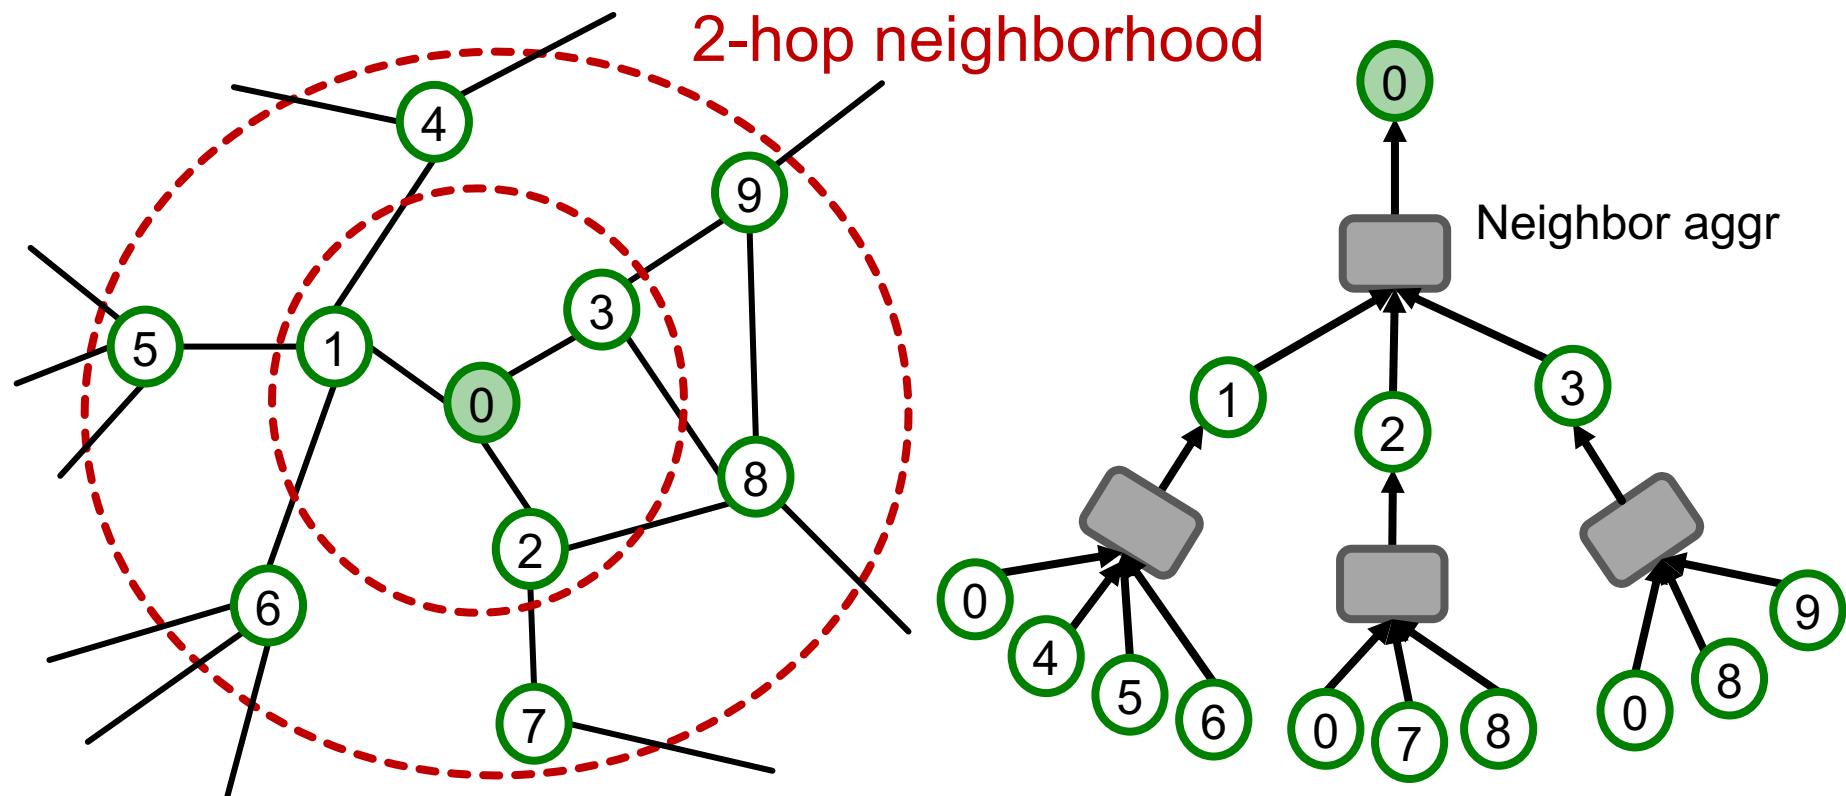

# Recall: Computational Graph

- **Recall:** GNNs generate node embeddings via neighbor aggregation.
  - Represented as a computational graph (right).

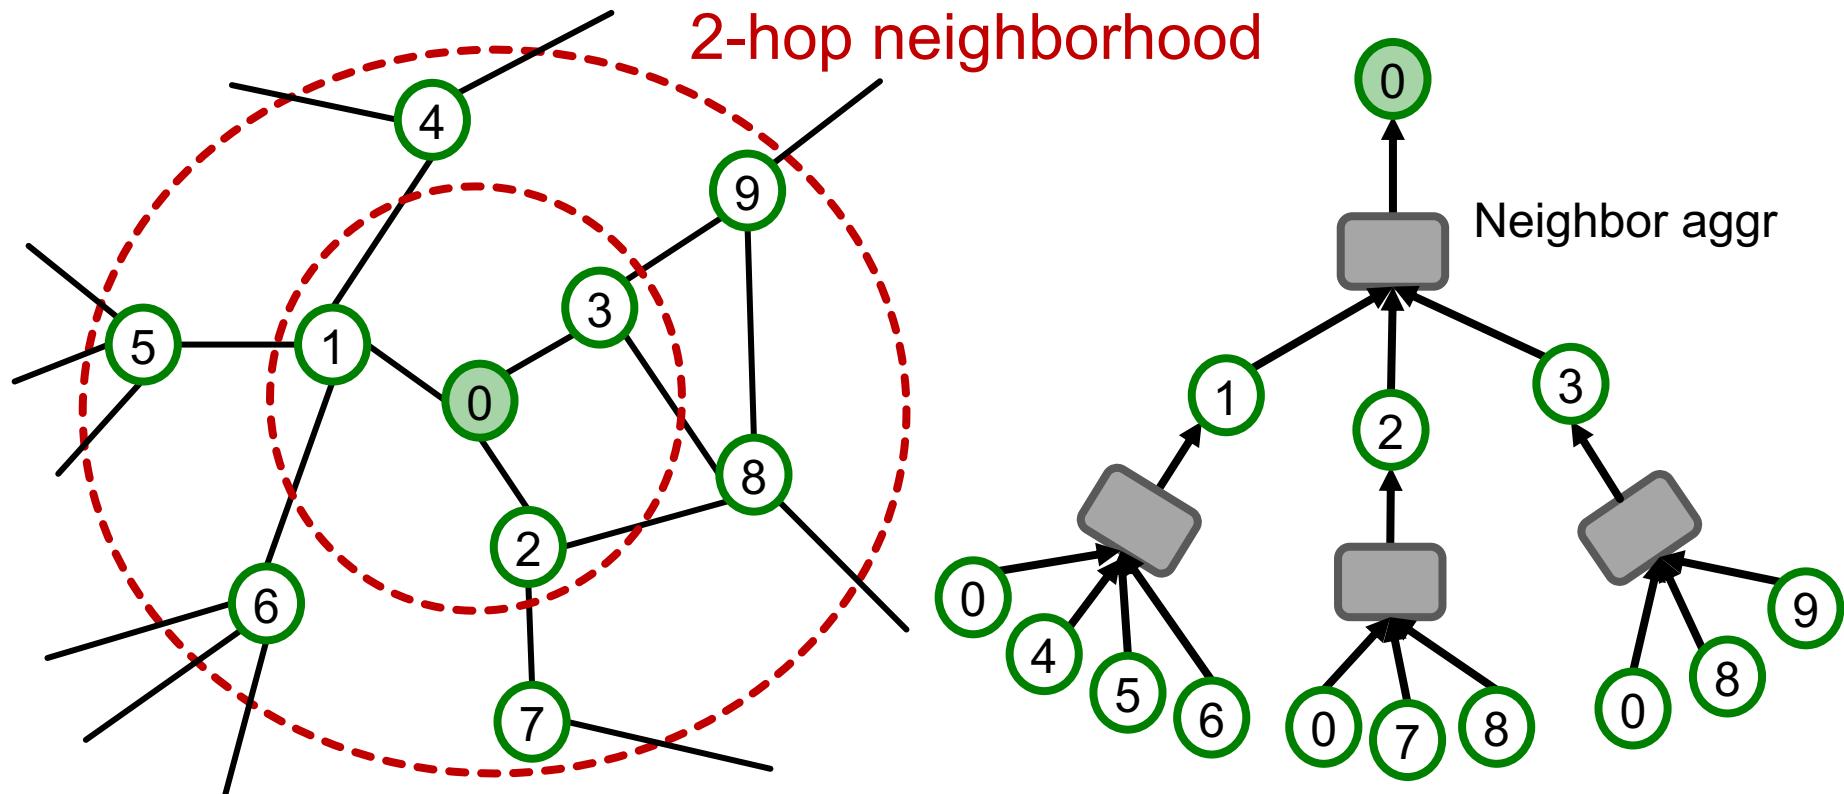

# Recall: Computational Graph

- **Observation:** A 2-layer GNN generates embedding of node “0” using 2-hop neighborhood structure and features.

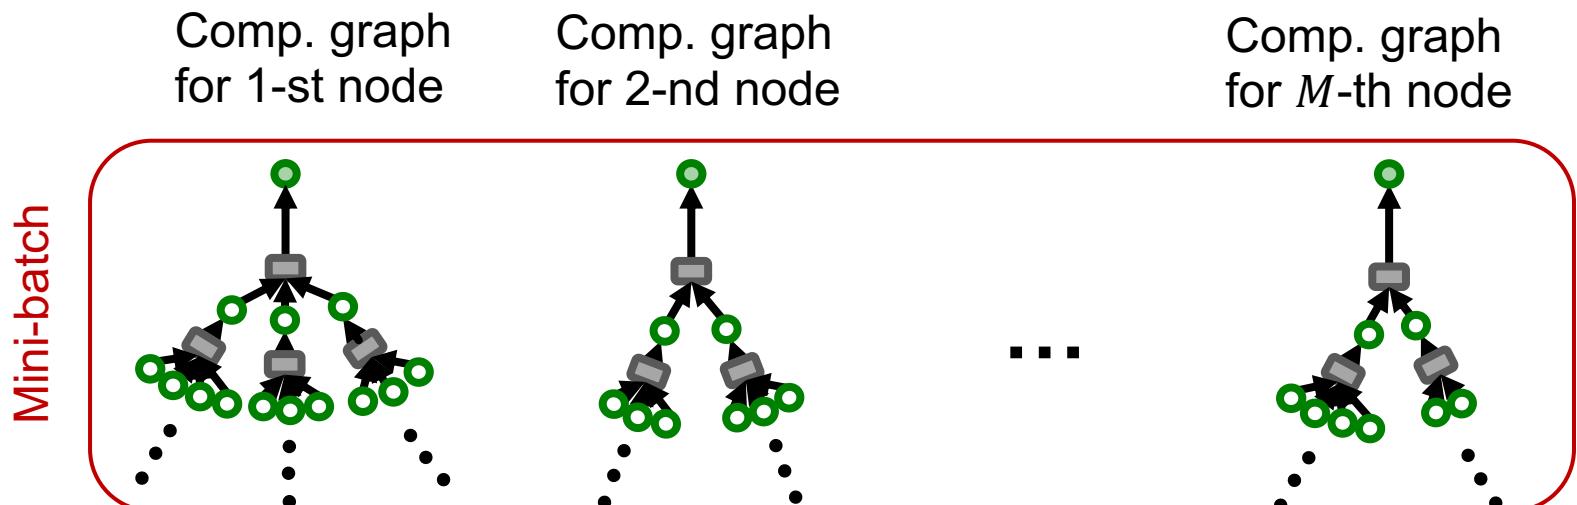

# Recall: Computational Graph

- **Observation:** More generally,  $K$ -layer GNNs generate embedding of a node using  $K$ -hop neighborhood structure and features.

# Computing Node Embeddings

- **Key insight:** To compute embedding of a single node, all we need is **the  $K$ -hop neighborhood** (which defines the computation graph).
- Given a set of  $M$  different nodes in a **mini-batch**, we can generate their embeddings using  $M$  computational graphs. **Can be computed on GPU!**

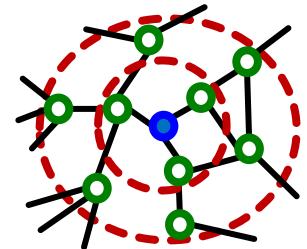

# Stochastic Training of GNNs

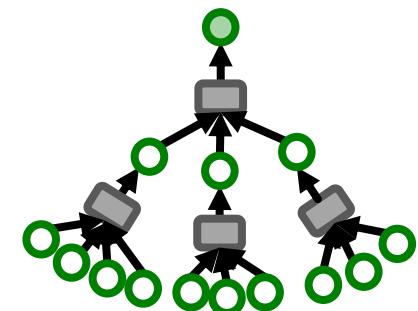

- We can now consider the following SGD strategy for training  $K$ -layer GNNs:

- Randomly sample  $M$  ( $\ll N$ ) nodes.
- For each sampled node  $v$ :
  - Get  **$K$ -hop neighborhood**, and construct the **computation graph**.
  - Use the above to generate  $v$ 's embedding.
- Compute the loss  $\ell_{sub}(\theta)$  averaged over the  $M$  nodes.
- Perform SGD:  $\theta \leftarrow \theta - \nabla \ell_{sub}(\theta)$

**$K$ -hop neighborhood**

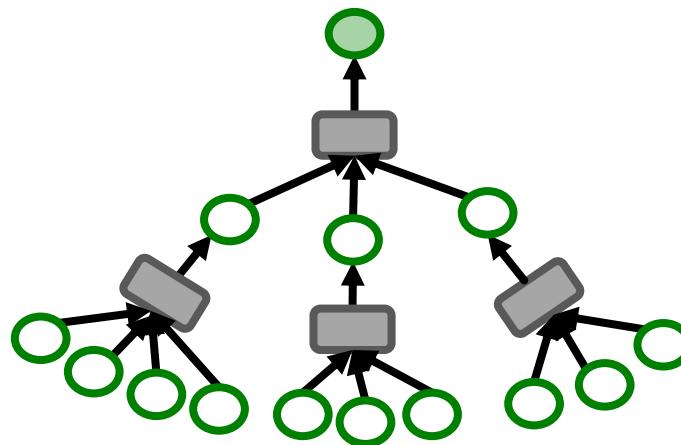

**Computational graph**

# Issue with Stochastic Training

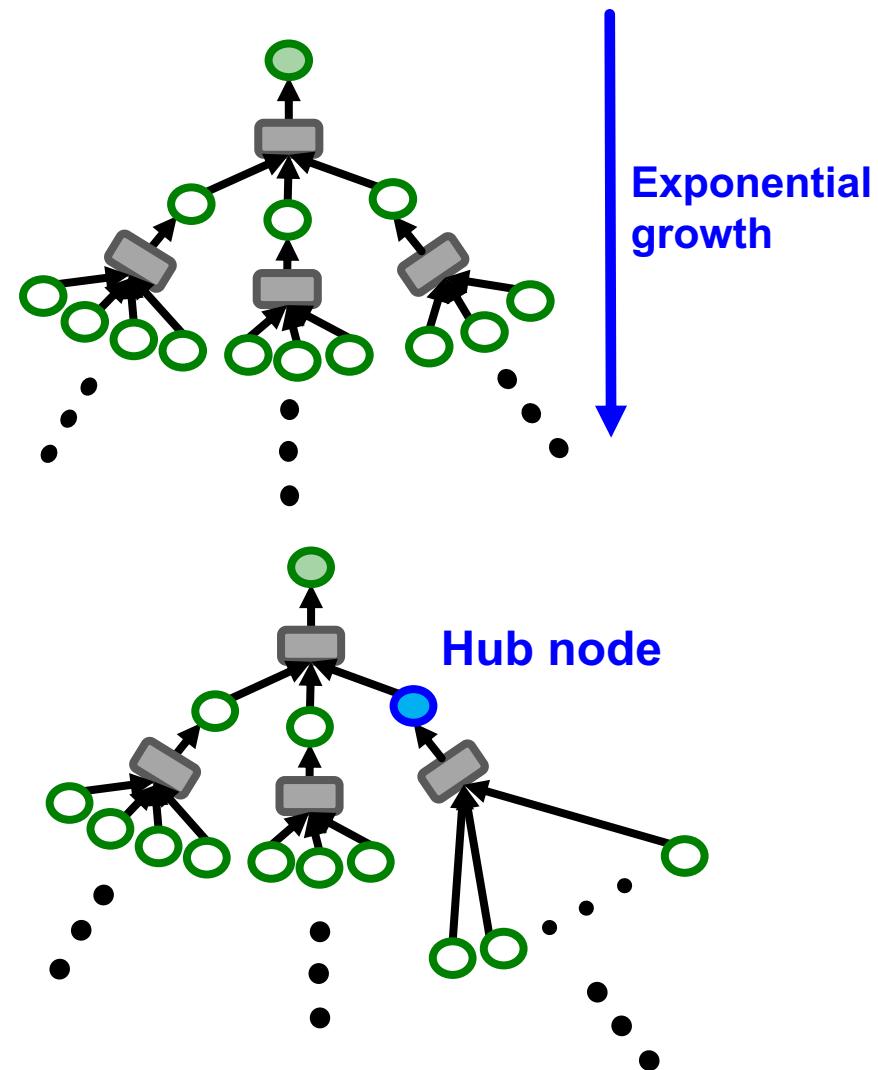

- For each node, we need to get the entire **K-hop neighborhood** and pass it through the computation graph.
- We need to aggregate lot of information just to compute one node embedding.
- **Computationally expensive.**

# Issue with Stochastic Training

## More details:

- Computation graph becomes **exponentially large** with respect to the layer size  $K$ .
- Computation graph explodes when it hits a **hub node** (high-degree node).
- Next:** Make the comp. graph more compact!

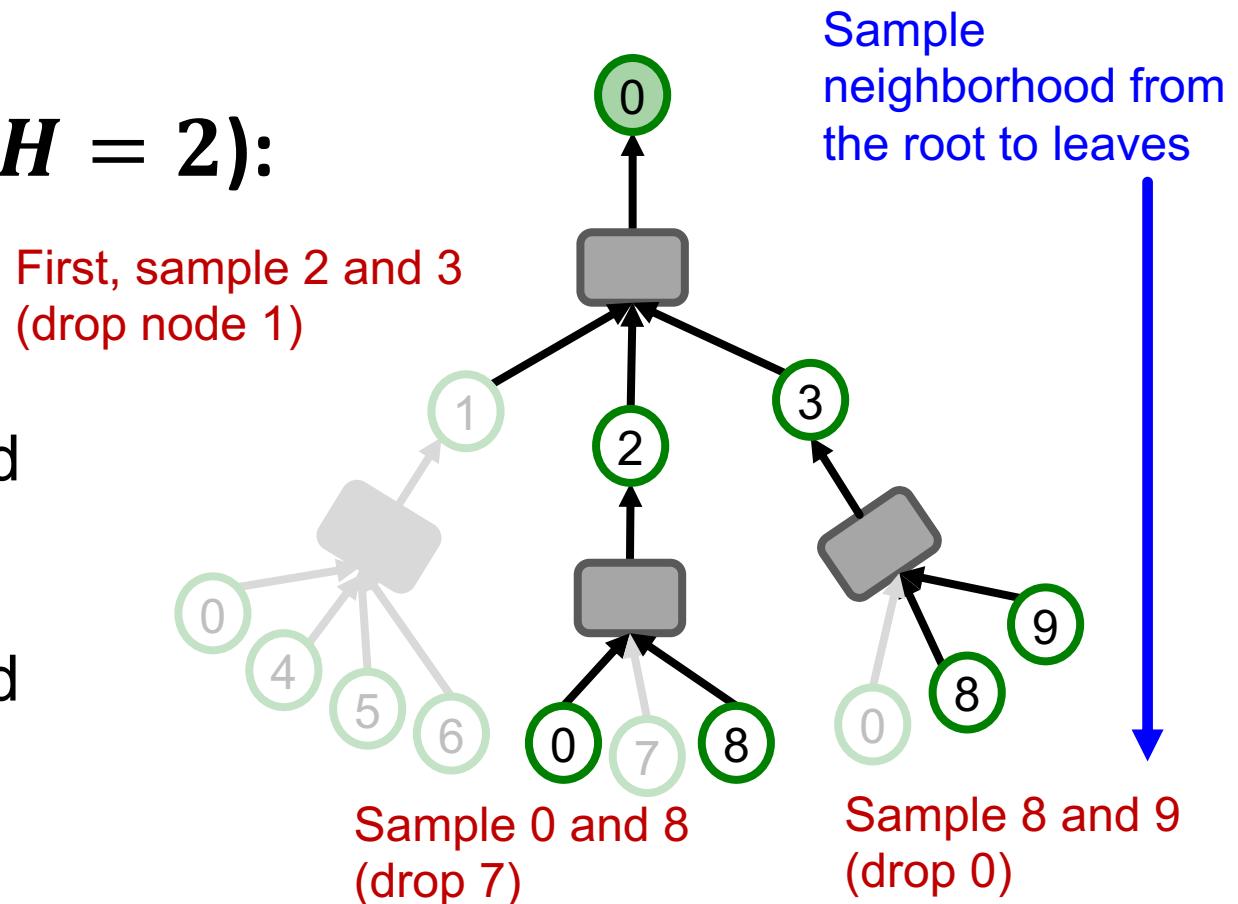

# Neighbor Sampling

**Key idea:** Construct the computational graph by (randomly) sampling at most  $H$  neighbors at each hop.

- Example ( $H = 2$ ):

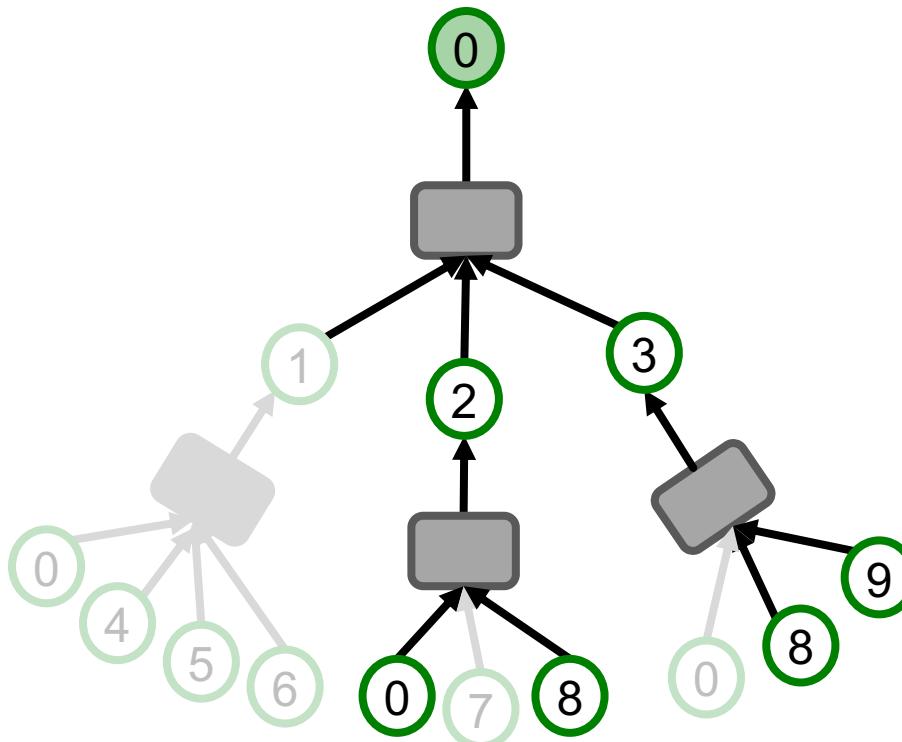

1<sup>st</sup>-hop neighborhood

2<sup>nd</sup>-hop neighborhood

# Neighbor Sampling

We can use the pruned computational graph to more efficiently compute node embeddings.

# Neighbor Sampling Algorithm

## Neighbor sampling for $K$ -layer GNN

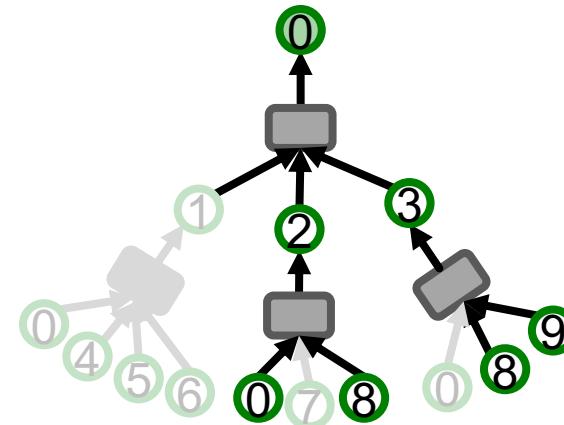

- For  $k = 1, 2, \dots, K$ :
  - For each node in  $k$ -hop neighborhood:
  - (Randomly) sample at most  $H_k$  neighbors:

**1<sup>st</sup>-hop neighborhood**

Sample  $H_1 = 2$  neighbors

**2<sup>nd</sup>-hop neighborhood**

Sample  $H_2 = 2$  neighbors

- $K$ -layer GNN will at most involve  $\prod_{k=1}^K H_k$  leaf nodes in comp. graph.

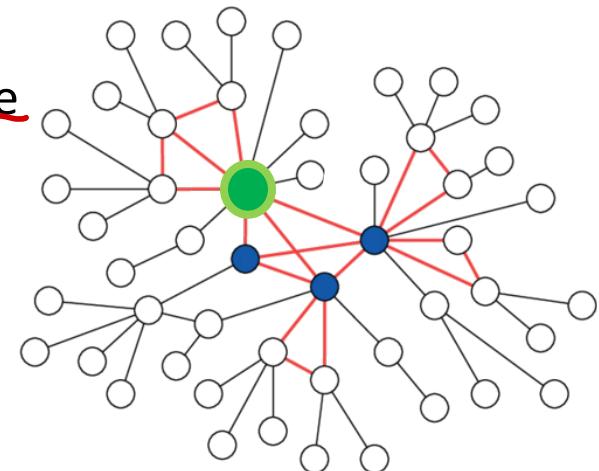

# Remarks on Neighbor Sampling (1)

- **Remark 1: Trade-off in sampling number  $H$** 
  - Smaller  $H$  leads to more efficient neighbor aggregation, but results in more unstable training  
**due to the larger variance** in neighbor aggregation.
- **Remark 2: Computational time**
  - Even with neighbor sampling, **the size of the computational graph is still exponential with respect to number of GNN layers  $K$ .**
  - Increasing one GNN layer would make computation  $H$  times more expensive.

# Remarks on Neighbor Sampling (2)

## ■ Remark 3: How to sample the nodes

- **Random sampling:** fast but many times not optimal (may sample many “unimportant” nodes)
- **Random Walk with Restarts:** *w restart scores*
  - Natural graphs are “scale free”, sampling random neighbors, samples many low degree “leaf” nodes.
  - Strategy to sample important nodes:
    - Compute Random Walk with Restarts score  $R_i$  starting at the **green** node
    - At each level sample  $H$  neighbors  $i$  with the highest  $R_i$
  - This strategy works much better in practice.

# Summary: Neighbor Sampling

- A computational graph is constructed for each node in a mini-batch.
- In neighbor sampling, the comp. graph is pruned/sub-sampled to increase computational efficiency.
- The pruned comp. graph is used to generate a node embedding.
- However, computational graphs can still become large, especially for GNNs with many message-passing layers. *Pinterest, Alibaba*

# Cluster-GCN: Scaling up GNNs

CS224W: Machine Learning with Graphs

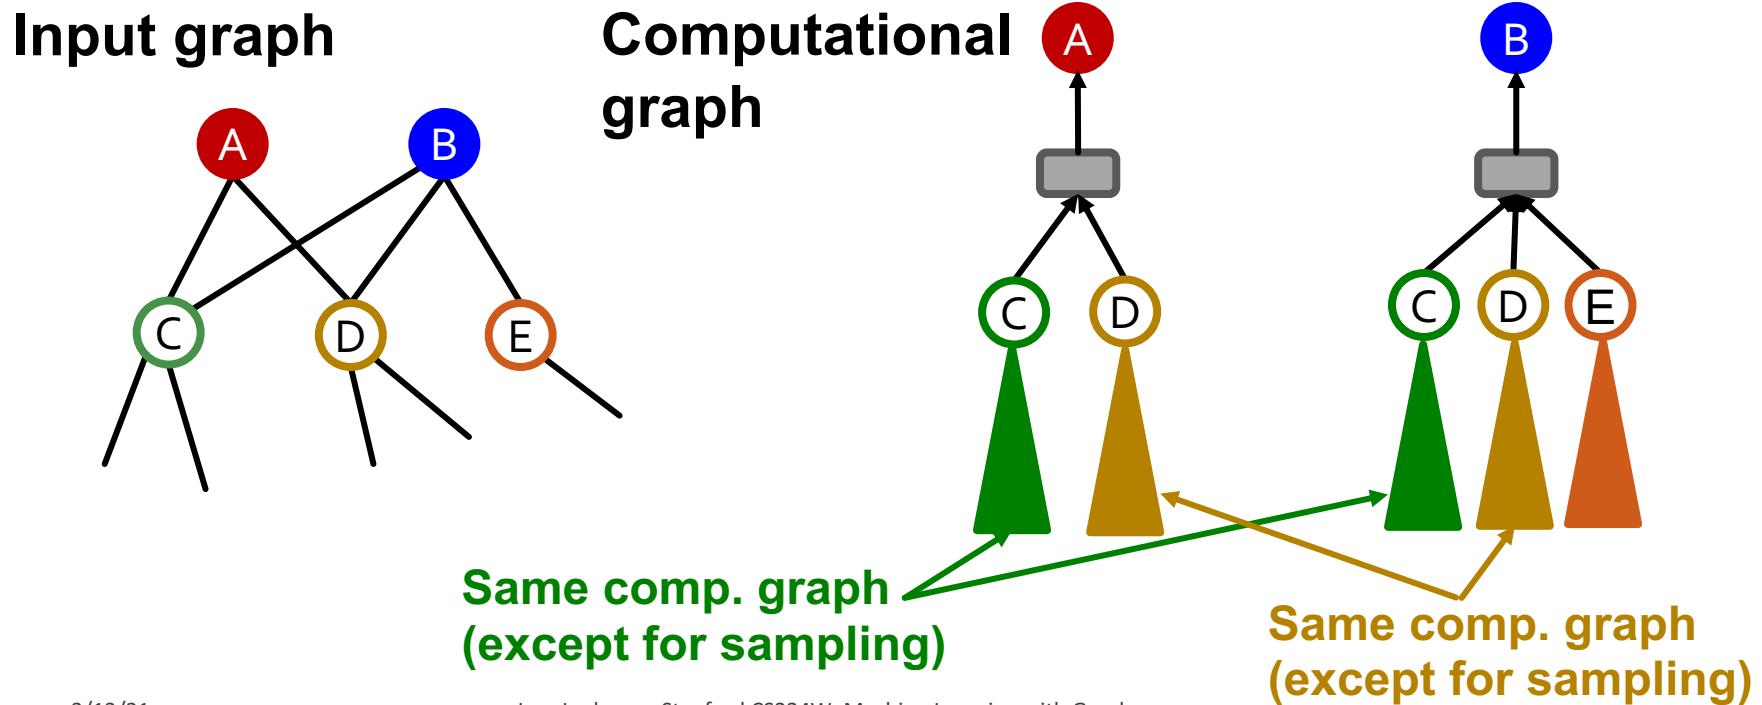

Jure Leskovec, Stanford University

<http://cs224w.stanford.edu>

# Issues with Neighbor Sampling

- The size of computational graph becomes exponentially large w.r.t. the #GNN layers.
- Computation is redundant, especially when nodes in a mini-batch share many neighbors.

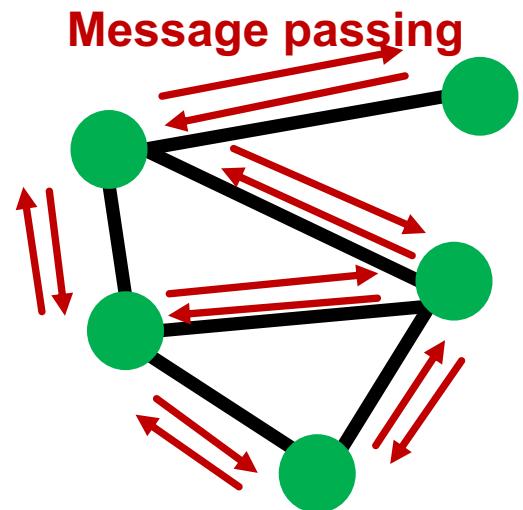

# Recall: Full Batch GNN

- In full-batch GNN implementation, **all the node embeddings are updated together using embeddings of the previous layer.**

Update for all  $v \in V$

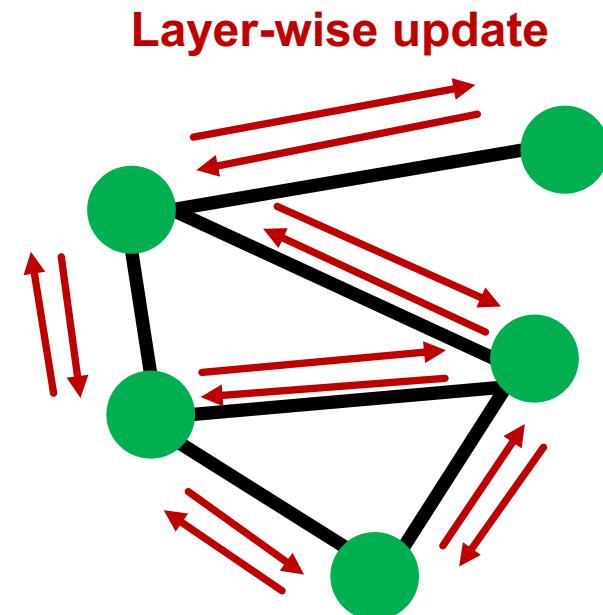

$$h_v^{(\ell)} = COMBINE \left( h_v^{(\ell-1)}, AGGR \left( \left\{ \mathbf{h}_u^{(\ell-1)} \right\}_{u \in N(v)} \right) \right)$$

- In each layer, only **2\*(#edges) messages** need to be computed.
- For  $K$ -layer GNN, only  $2K * \#(\text{edges})$  messages need to be computed.
- GNN's entire computation is only **linear** in  $\#(\text{edges})$  and  $\#(\text{GNN layers})$ . **Fast!**

# Insight from Full-batch GNN

- The **layer-wise** node embedding update allows the **re-use** of embeddings from the previous layer.
- This significantly **reduces** the **computational redundancy** of neighbor sampling.
  - Of course, the **layer-wise** update is **not feasible** for a large graph due to **limited GPU memory**.

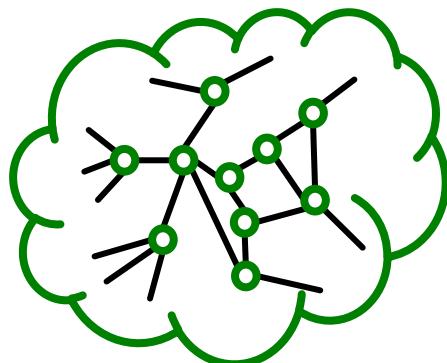

# Subgraph Sampling

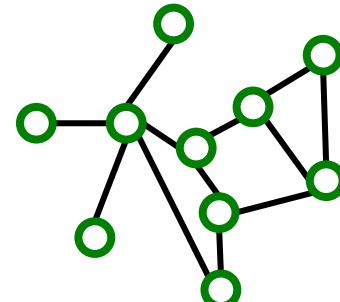

- **Key idea:** We can **sample a small subgraph of the large graph** and then perform the efficient **layer-wise** node embeddings update over the subgraph.

Full Batch GNN  $\Rightarrow$  간접.

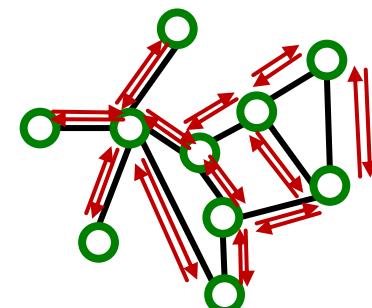

Large graph

Sampled subgraph  
(small enough to  
be put on a GPU)

Layer-wise  
node embeddings  
update on the GPU

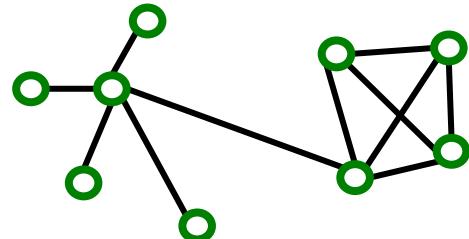

# Subgraph Sampling

- **Key question:** What subgraphs are good for training GNNs?
  - Recall: GNN performs node embedding by passing messages **via the edges**.
    - Subgraphs **should retain edge connectivity structure of the original graph as much as possible.**
    - This way, the GNN over the subgraph generates embeddings closer to the GNN over the original graph.

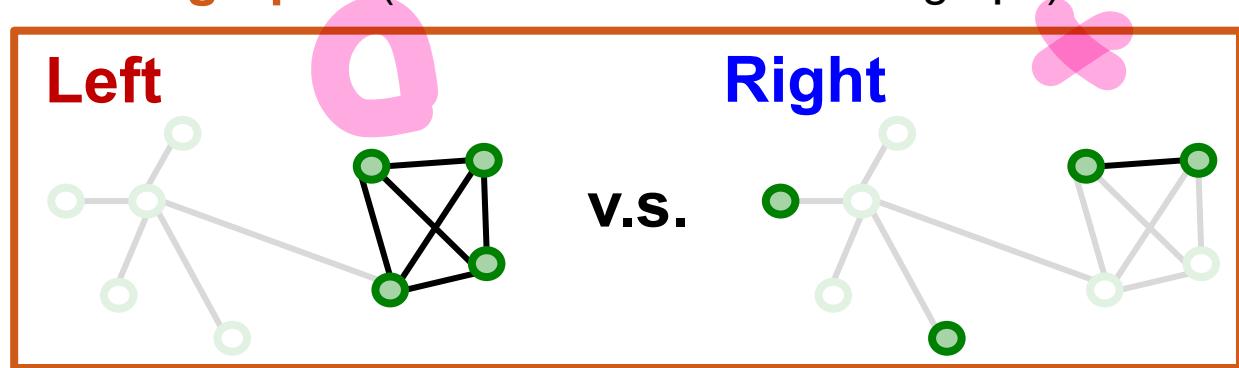

# Subgraph Sampling: Case Study

- Which subgraph is good for training GNN?

Original graph

Subgraphs (both 4-node induced subgraph)

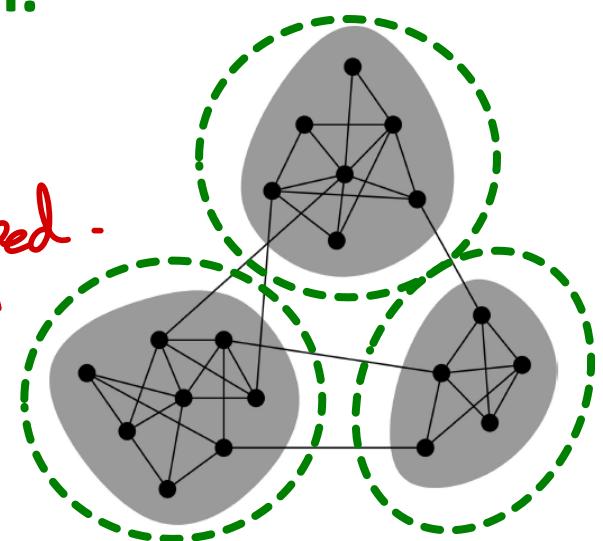

- **Left subgraph** retains the essential community structure among the 4 nodes → **Good**
- **Right subgraph** drops many connectivity patterns, even leading to isolated nodes → **Bad**

# Exploiting Community Structure

Real-world graph exhibits community structure

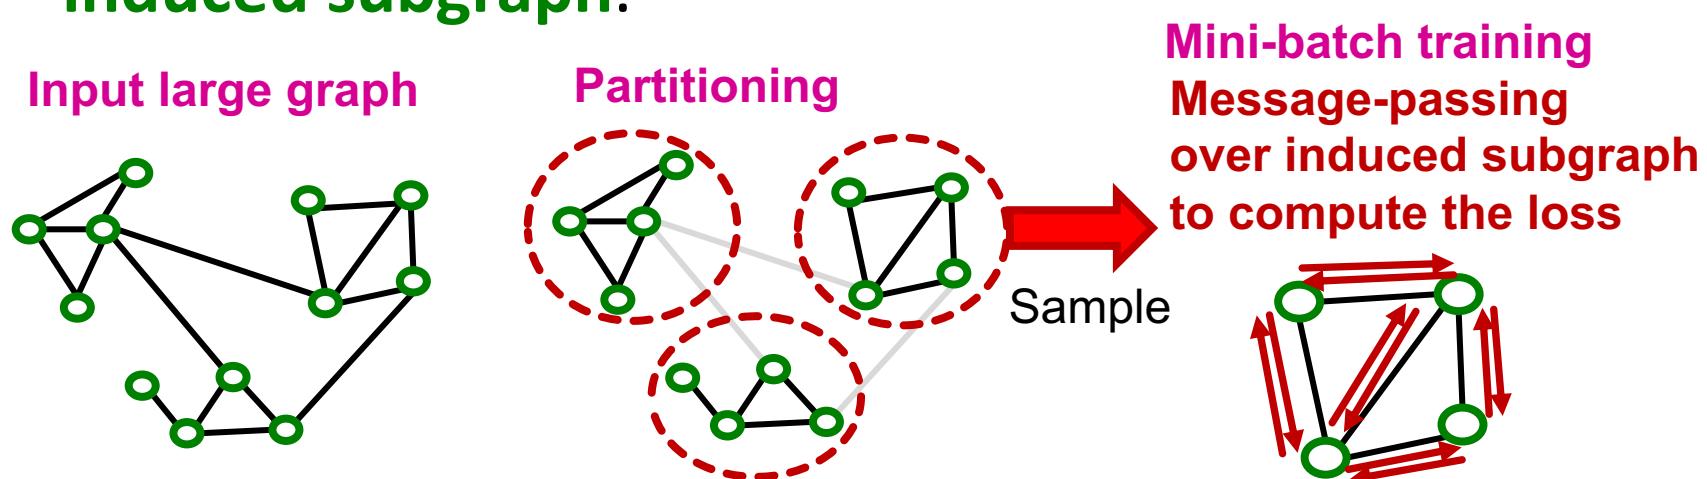

- A large graph can be decomposed into many small communities.
- **Key insight** [Chiang et al. KDD 2019]:  
**Sample a community as a subgraph.**  
**Each subgraph retains essential local connectivity pattern of the original graph.**

*Only few edges dropped -*

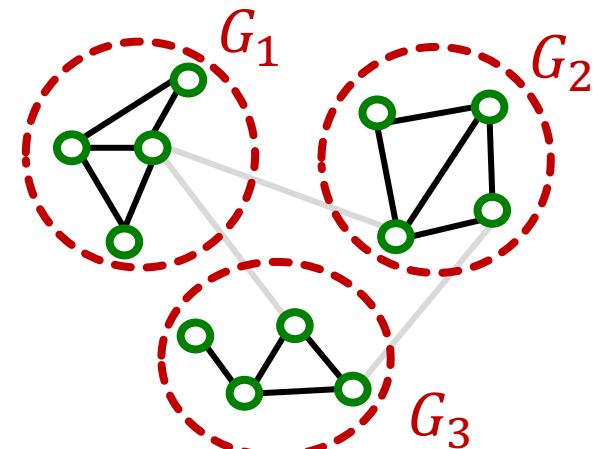

# Cluster-GCN: Overview

- We first introduce “vanilla” Cluster-GCN.
- Cluster-GCN consists of two steps:
  - **Pre-processing**: Given a large graph, partition it into groups of nodes (i.e., subgraphs).
  - **Mini-batch training**: Sample one node group at a time. Apply GNN’s message passing over the **induced subgraph**.

# Cluster-GCN: Pre-processing

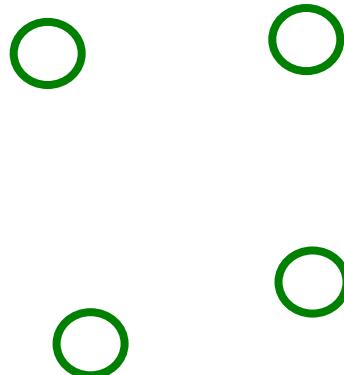

- Given a large graph  $G = (V, E)$ , **partition its nodes  $V$  into  $C$  groups:**  $V_1, \dots, V_C$ .
    - We can use any scalable community detection methods, e.g., Louvain, METIS [Karypis et al. SIAM 1998].
  - $V_1, \dots, V_C$  induces  $C$  subgraphs,  $G_1, \dots, G_C$ ,
    - Recall:  $G_c \equiv (V_c, E_c)$ ,
    - where  $E_c = \{(u, v) | u, v \in V_c\}$
- Notice: Between-group edges are *not* included in  $G_1, \dots, G_C$ .**

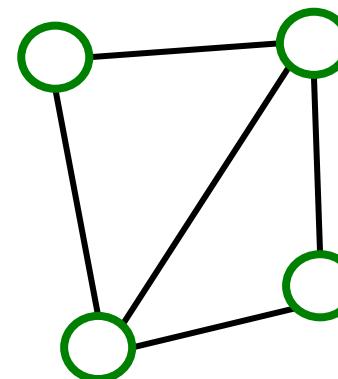

# Cluster-GCN: Mini-batch Training

- For each mini-batch, **randomly sample a node group  $V_c$ .**
- Construct **induced subgraph  $G_c = (V_c, E_c)$**

Sampled node group  $V_c$

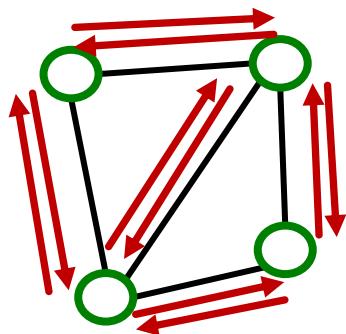

Induced subgraph  $G_c$

# Cluster-GCN: Mini-batch Training

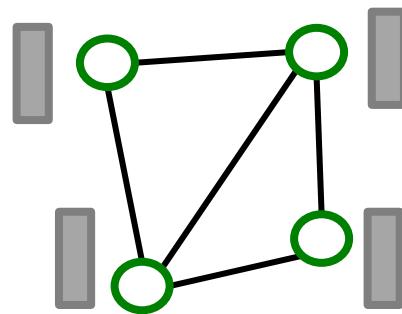

- Apply GNN's **layer-wise node update** over  $G_c$  to obtain embedding  $\mathbf{h}_v$  for each node  $v \in V_c$ .
- Compute the loss for each node  $v \in V_c$  and take average:  $\ell_{sub}(\theta) = (1/|V_c|) \cdot \sum_{v \in V_c} \ell_v(\theta)$
- Update params:  $\theta \leftarrow \theta - \nabla \ell_{sub}(\theta)$

Induced subgraph  $G_c$

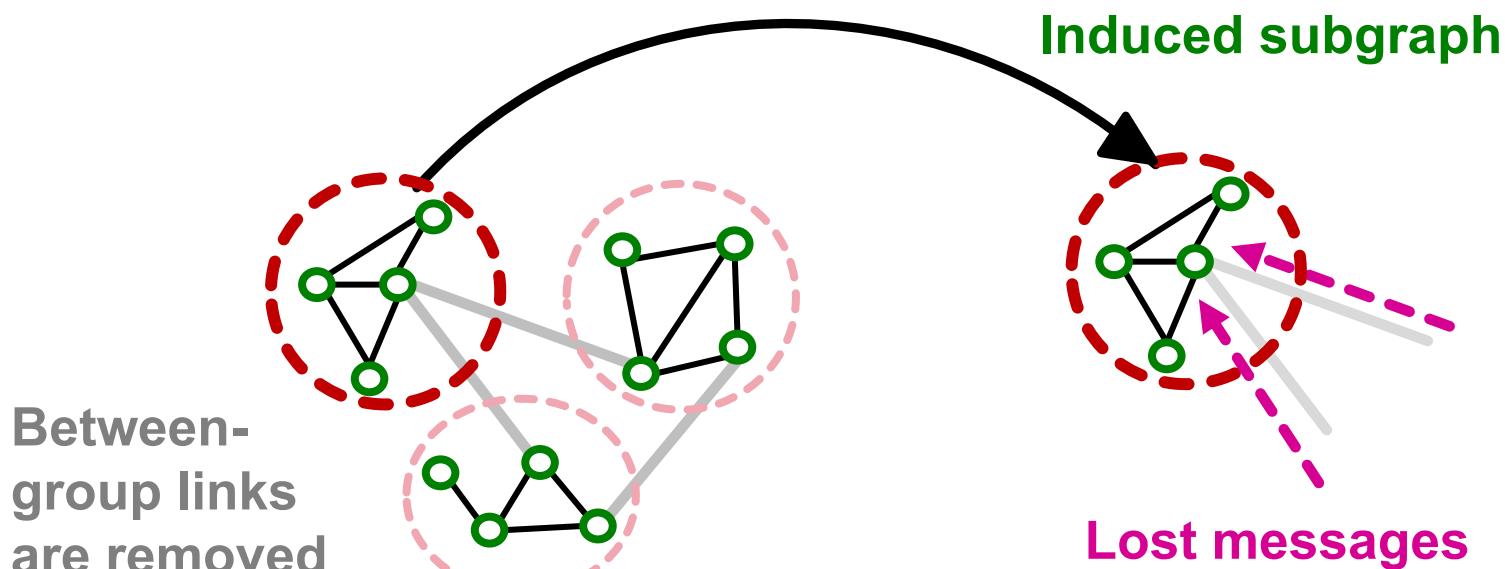

Layer-wise node  
embedding update

Embedding

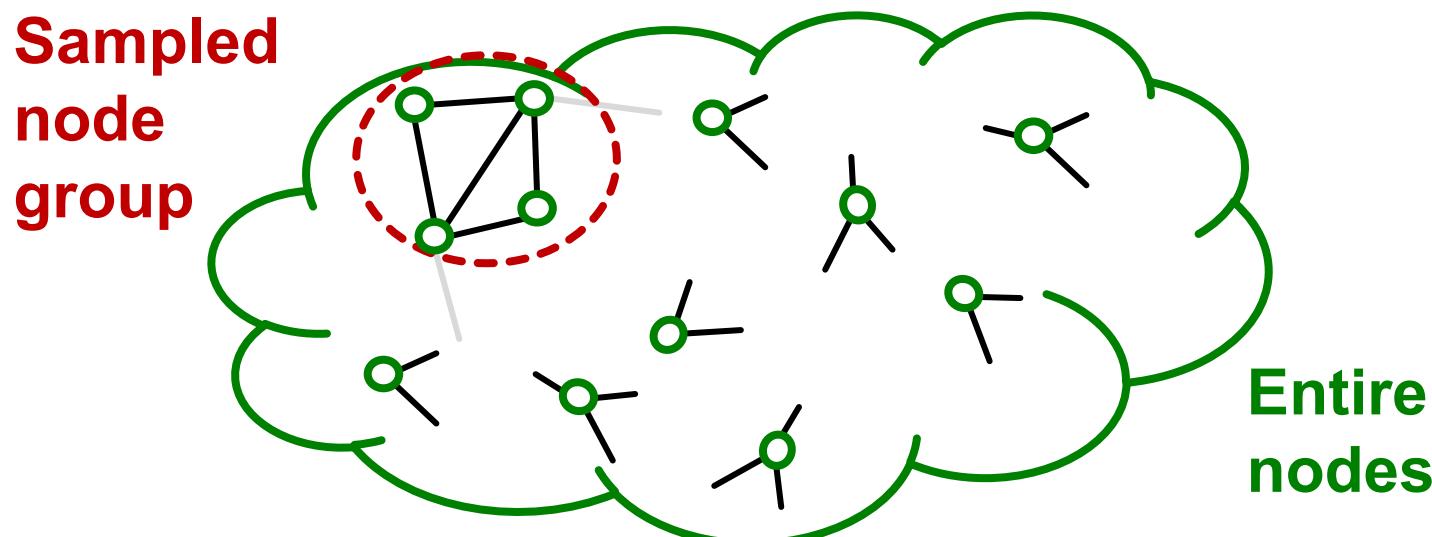

# Issues with Cluster-GCN (1)

- The induced subgraph removes between-group links.
- As a result, messages from other groups will *be lost during message passing*, which could hurt the GNN's performance.

# Issues with Cluster-GCN (2)

- Graph community detection algorithm **puts similar nodes together in the same group.**
- **Sampled node group** tends to only cover the small-concentrated portion of the **entire data**.

# Issues with Cluster-GCN (3)

Sampled nodes are not diverse enough to be represent the entire graph structure:

- As a result, the gradient averaged over the sampled nodes,  $\frac{1}{|V_c|} \sum_{v \in V_c} \nabla \ell_v(\theta)$ , becomes unreliable.
  - Fluctuates a lot from a node group to another.
  - In other words, the gradient has high variance.
- Leads to slow convergence of SGD

# Advanced Cluster-GCN: Overview

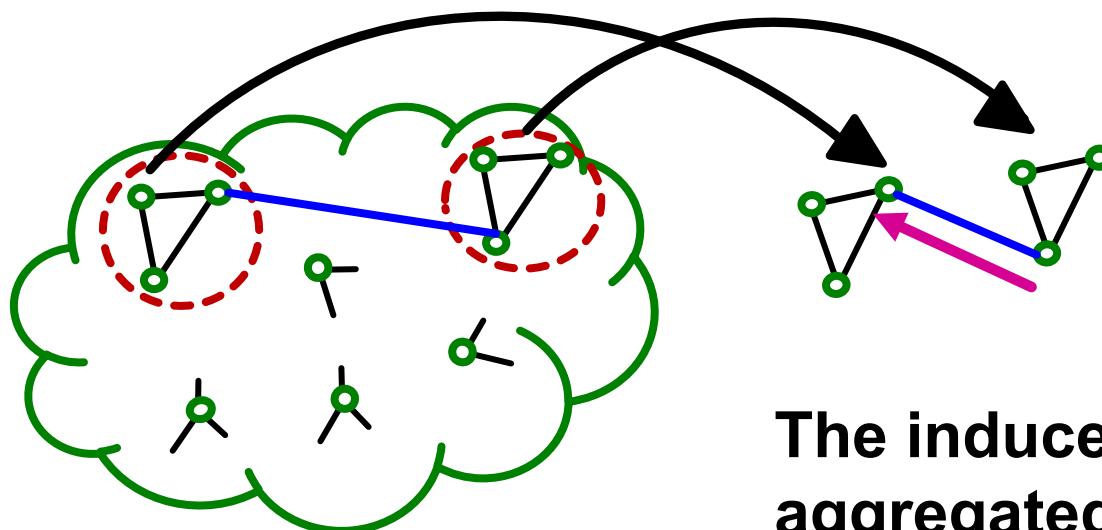

- **Solution: Aggregate multiple node groups per mini-batch.**
- Partition the graph into **relatively-small groups of nodes**.
- **For each mini-batch:**
  - Sample and aggregate **multiple node groups**.
  - **Construct the induced subgraph of the *aggregated node group*.**
  - The rest is the same as vanilla Cluster-GCN (compute node embeddings and the loss, update parameters)

# Advanced Cluster-GCN: Overview

## ■ Why does the solution work?

### Sampling **multiple node groups**

→ Makes the sampled nodes more representative of the entire nodes. Leads to less variance in gradient estimation.

**The induced subgraph over aggregated node groups**

- Includes between-group edges
- Message can flow across groups.

# Advanced Cluster-GCN

Similar to vanilla Cluster-GCN, advanced Cluster-GCN also follows 2-step approaches.

## Pre-processing step:

- Given a large graph  $G = (V, E)$ , partition its nodes  $V$  into  $C$  **relatively-small** groups:  
 $V_1, \dots, V_C$ .
  - $V_1, \dots, V_C$  needs to be small so that even if multiple of them are aggregated, the resulting group would not be too large.

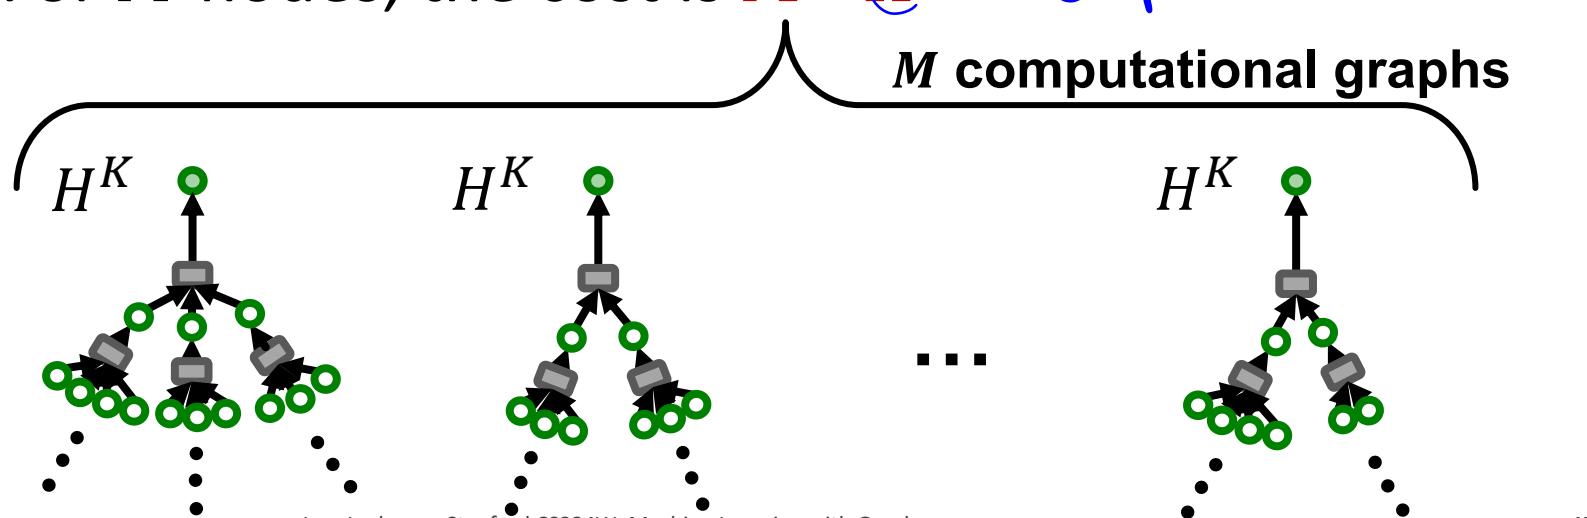

# Advanced Cluster-GCN

## Mini-batch training:

- For each mini-batch, **randomly sample a set of  $q$  node groups:**  $\{V_{t_1}, \dots, V_{t_q}\} \subset \{V_1, \dots, V_C\}$ .
- **Aggregate all nodes across the sampled node groups:**  $V_{aggr} = V_{t_1} \cup \dots \cup V_{t_q}$
- Extract the **induced subgraph**  
 $G_{aggr} = (V_{aggr}, E_{aggr}),$   
where  $E_{aggr} = \{(u, v) \mid u, v \in V_{aggr}\}$ 
  - $E_{aggr}$  also includes between-group edges!

# Comparison of Time Complexity

- Generate  $M$  ( $<< N$ ) node embeddings using  $K$ -layer GNN ( $N$  : #all nodes).
- Neighbor-sampling (sampling  $H$  nodes per layer):
  - For each node, the size of  $K$ -layer computational graph is  $H^K$ .
  - For  $M$  nodes, the cost is  $M \cdot H^K$

# Comparison of Time Complexity

- Generate  $M$  ( $<< N$ ) node embeddings using  $K$ -layer GNN ( $N$  : #all nodes).
- Cluster-GCN:
  - Perform message passing over a subgraph induced by the  $M$  nodes.
  - The subgraph contains  $M \cdot D_{avg}$  edges, where  $D_{avg}$  is the average node degree.
  - $K$ -layer message passing over the subgraph costs at most  $K \cdot M \cdot D_{avg}$ .

# Comparison of Time Complexity

- In summary, the cost to generate embeddings for  $M$  nodes using  $K$ -layer GNN is:
  - **Neighbor-sampling (sample  $H$  nodes per layer):**  
 $M \cdot H^K$
  - **Cluster-GCN:**  $K \cdot M \cdot D_{avg}$
- Assume  $H = D_{avg}/2$ . In other words, 50% of neighbors are sampled.
  - Then, Cluster-GCN (cost:  $2MHK$ ) is much more efficient than neighbor sampling (cost:  $MH^K$ ).
  - Linear (instead of exponential) dependency w.r.t.  $K$ .

# Cluster-GCN: Summary

- Cluster-GCN first **partitions the entire nodes into a set of small node groups.**
- At each mini-batch, multiple node groups are sampled, and their nodes are aggregated.
- **GNN performs layer-wise node embeddings update over the induced subgraph.**
- Cluster-GCN is more computationally efficient than neighbor sampling, especially when #(GNN layers) is large.  
*flexibility, 31% vs 48%*
- But Cluster-GCN leads to systematically biased gradient estimates (due to missing cross-community edges)

# Scaling up by Simplifying GNNs

CS224W: Machine Learning with Graphs

Jure Leskovec, Stanford University

<http://cs224w.stanford.edu>

# Roadmap of Simplifying GCN

- We start from Graph Convolutional Network (GCN) [Kipf & Welling ICLR 2017].
- We simplify GCN by **removing the non-linear activation** from the GCN [Wu et al. ICML 2019].
  - *Wu et al.* demonstrated that the performance on benchmark is not much lower by the simplification.
- Simplified GCN turns out to be extremely scalable by the model design.

# Recall: GCN (mean-pool)

- **Given:** Graph  $G = (V, E)$  with input node features  $X_v$  for  $v \in V$ , where  **$E$  includes the self-loop**:
    - $(v, v) \in E$  for all  $v \in V$ .
  - Set input node embeddings:  $h_v^{(0)} = X_v$  for  $v \in V$ .

- Set input node embeddings:  $h_\nu^{(0)} = X_\nu$  for  $\nu \in V$
  - For  $k \in \{0, \dots, K - 1\}$ :
    - For all  $\nu \in V$ , aggregate neighboring information as

$$h_v^{(k+1)} = \text{ReLU} \left( W_k \begin{pmatrix} \frac{1}{|N(v)|} \sum_{u \in N(v)} h_u^{(k)} \end{pmatrix} \right)$$

Trainable weight matrices  
(i.e., what we learn)      Mean-pooling

- **Final node embedding:**  $z_v = h_v^{(K)}$

# Recall: Matrix Formulation of GCN

GCN aggregations can be formulated as matrix vector product:

- Let  $\mathbf{H}^{(k)} = [h_1^{(k)} \dots h_{|V|}^{(k)}]^T$
- Let  $\mathbf{A}$  be the adjacency matrix (w/ self-loop)
- Then:  $\sum_{u \in N(v)} h_u^{(k)} = A_{v,:} \mathbf{H}^{(k)}$
- Let  $\mathbf{D}$  be diagonal matrix where  $D_{v,v} = \text{Deg}(v) = |N(v)|$ 
  - The inverse of  $D$ :  $D^{-1}$  is also diagonal:  
$$D_{v,v}^{-1} = 1/|N(v)|$$
- Therefore,

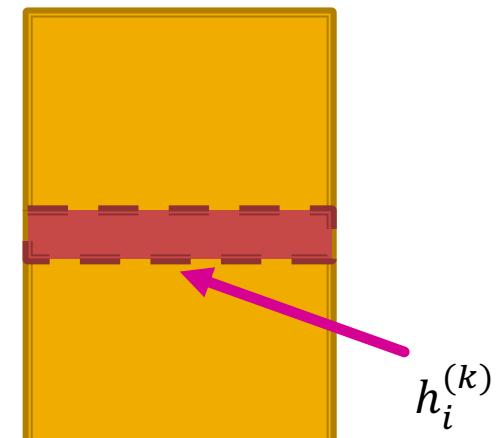

$$\frac{1}{|N(v)|} \sum_{u \in N(v)} h_u^{(k)}$$

$$\mathbf{H}^{(k+1)} = D^{-1} \mathbf{A} \mathbf{H}^{(k)}$$

$$D^{-1} \mathbf{A} \mathbf{H}^{(k)}$$

Matrix of hidden embeddings  $\mathbf{H}^{(k)}$

# Recall: Matrix Formulation of GCN

- GCN's neighbor aggregation:

$$h_v^{(k+1)} = \text{ReLU} \left( W_k \frac{1}{|N(v)|} \sum_{u \in N(v)} h_u^{(k)} \right)$$

- In matrix form:

$$\mathbf{H}^{(k+1)} = \text{ReLU}(\tilde{\mathbf{A}} \mathbf{H}^{(k)} \mathbf{W}_k^T)$$

where  $\tilde{\mathbf{A}} = \mathbf{D}^{-1} \mathbf{A}$ .

- Note: The original GCN uses re-normalized version:  $\tilde{\mathbf{A}} = \mathbf{D}^{-1/2} \mathbf{A} \mathbf{D}^{-1/2}$ .

- Empirically, this version of  $\tilde{\mathbf{A}}$  often gives better performance than  $\mathbf{D}^{-1} \mathbf{A}$ .

# Simplifying GCN

- Simplify GCN by removing **ReLU non-linearity**:

$$H^{(k+1)} = \tilde{A} H^{(k)} W_k^T$$

- The final node embedding matrix is given as

$$H^{(K)} = \tilde{A} H^{(K-1)} W_{K-1}^T$$

$$= \tilde{A} (\tilde{A} H^{(K-2)} W_{K-2}^T) W_{K-1}^T$$

$$\dots = \tilde{A} (\tilde{A} (\dots (\tilde{A} H^{(0)} W_0^T) \dots) W_{K-2}^T) W_{K-1}^T$$

$$= \tilde{A}^K X (W_0^T \dots W_{K-1}^T)$$

Composition of linear transformation is still linear!

$$= \tilde{A}^K X W^T$$

where  $W \equiv W_{K-1} \dots W_0$

# Simplifying GCN (1)

- Removing ReLU significantly simplifies GCN!

$$\mathbf{H}^{(K)} = \tilde{\mathbf{A}}^K \mathbf{X} \mathbf{W}^T$$

- Notice  $\tilde{\mathbf{A}}^K \mathbf{X}$  does not contain any learnable parameters; hence, it **can be pre-computed.**
  - Efficiently computable as a sequence of sparse-matrix vector products:
  - Do  $\mathbf{X} \leftarrow \tilde{\mathbf{A}} \mathbf{X}$  for  $K$  times.

# Simplifying GCN (2)

- Let  $\tilde{X} = \tilde{A}^K X$  be pre-computed matrix.
- Simplified GCN's final embedding is

$$H^{(K)} = \tilde{X} W^T$$

- It's just a **linear transformation of pre-computed matrix!**
- Back to the node embedding form:

$$h_v^{(K)} = W \boxed{\tilde{X}_v}$$

Pre-computed feature vector for node  $v$

- Embedding of node  $v$  only depends on its own (pre-processed) feature!

# Simplifying GCN (3)

- Once  $\tilde{X}$  is pre-computed, embeddings of  $M$  nodes can be generated in time linear in  $M$ :
  - Given  $M$  nodes  $\{\nu_1, \nu_2, \dots, \nu_M\}$ , their embeddings are
    - $h_{\nu_1}^{(K)} = \mathbf{W}\tilde{X}_{\nu_1}$ ,
    - $h_{\nu_2}^{(K)} = \mathbf{W}\tilde{X}_{\nu_2}$ ,
    - ...
    - $h_{\nu_M}^{(K)} = \mathbf{W}\tilde{X}_{\nu_M}$ .

# Simplified GCN: Summary

In summary, simplified GCN consists of **two steps**:

- **Pre-processing step:**

- Pre-compute  $\tilde{X} = \tilde{A}^K X$ . Can be done on CPU.

- **Mini-batch training step:**

- For each mini-batch, randomly-sample  $M$  nodes  $\{v_1, v_2, \dots, v_M\}$ .
  - Compute their embeddings by → 한 번에 몇개?
    - $h_{v_1}^{(K)} = W\tilde{X}_{v_1}, h_{v_2}^{(K)} = W\tilde{X}_{v_2}, \dots, h_{v_M}^{(K)} = W\tilde{X}_{v_M}$
  - Use the embeddings to make prediction and compute the loss averaged over the  $M$  data points.
  - Perform SGD parameter update.

# Comparison with Other Methods

- **Compared to neighbor sampling:**
  - Simplified GCN generates node embeddings much more efficiently (no need to construct the giant computational graph for each node).
- **Compared to Cluster-GCN:**
  - Mini-batch nodes of simplified GCN can be sampled completely randomly from the entire nodes (no need to sample from multiple groups as Cluster-GCN does)
  - Leads to lower SGD variance during training.
- But the model is much **less expressive** (next).

# Potential Issue of Simplified GCN

- Compared to the original GNN models,  
**simplified GCN's expressive power is limited  
due to the lack of non-linearity in generating  
node embeddings.**

# Performance of Simplified GCN

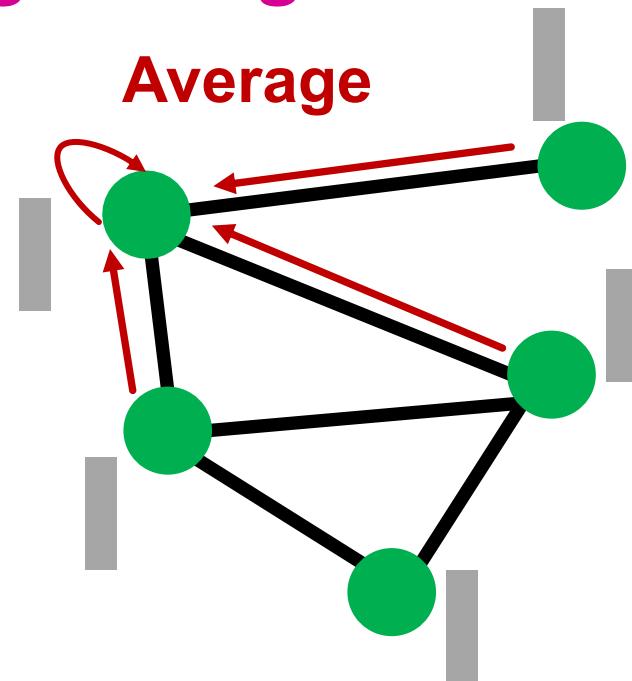

- Surprisingly, in semi-supervised node classification benchmark, **simplified GCN works comparably to the original GNNs despite being less expressive.**
- **Why?**

# Graph Homophily

- Many node classification tasks exhibit homophily structure, i.e., **nodes connected by edges tend to share the same target labels.**
- **Examples:**
  - Paper category classification in paper-citation network
    - Two papers tend to share the same category if one cites another.
  - Movie recommendation for users in social networks
    - Two users tend to like the same movie if they are friends in a social network.

# When does Simplified GCN Work?

- Recall the preprocessing step of the simplified GCN: **Do  $X \leftarrow \tilde{A} X$  for  $K$  times.**
- Pre-processed features are obtained **by iteratively averaging their neighboring node features.**
- As a result, nodes connected by edges tend to have similar pre-processed features.

# When does Simplified GCN Work?

- **Premise:** Model uses the pre-processed node features to make prediction.
- Nodes connected by edges tend to get similar pre-processed features.  
→ **Nodes connected by edges tend to be predicted the same labels by the model**
- **Simplified SGC's prediction aligns well with the graph homophily in many node classification benchmark datasets.**

# Simplified GCN: Summary

- **Simplified GCN removes non-linearity in GCN and reduces to the simple pre-processing of node features.**
- Once the pre-processed features are obtained, scalable mini-batch SGD can be directly applied to optimize the parameters.
- **Simplified GCN works surprisingly well in node classification benchmark.**
  - The feature pre-processing aligns well with graph homophily in real-world prediction tasks.
